

Finance Operations

Hosting on AWS — Overview & Recommendation

Prepared for Sunshine • 24 July 2026 • Prepared by UpsureAI

In short

You have asked to host Finance Operations on your own AWS account while keeping Supabase — the database that stores your data and manages sign-in — exactly as it is today. This is a clean, low-risk move. The application is packaged into standard containers and runs on a single AWS server; Supabase stays untouched, so login and your existing data continue to work without any migration. It is a re-hosting exercise, not a rebuild.

Server	1 x AWS EC2 t3.large (2 vCPU / 8 GB) - comfortable for your team
Region	Mumbai (ap-south-1) - same region as your Supabase database
Database & login	Supabase, unchanged - no data migration, no re-work
Capacity	Comfortable for 15-20 daily users, with headroom for ~50 at peak
Est. running cost	~\$70 / month (about ~\$50 on a 1-year commitment)
Effort	A short, planned deployment by our AWS engineer

How it will be set up

Your two application parts (the screens you use, and the engine behind them) run on one AWS server behind a secure gateway that provides HTTPS. They talk to Supabase in the same region for fast response.

What it costs and how it performs

Figure 1 — The full monthly cost of running on AWS. The server itself is the main item; a one-year commitment lowers the total. *Domain fee spread across the year.

Figure 2 — Placing the server in Mumbai, the same region as your database, keeps the app fast by avoiding a longer network trip.

Figure 3 — The chosen server has ample spare capacity: even the most demanding moment uses well under half its memory, leaving plenty of room for busy periods.

The domain name (web address)

The application needs a proper web address (for example **finance.yourcompany.com**). This is required, not optional — a secure HTTPS connection can only be issued to a real domain name, and a financial application must always run over HTTPS. If a suitable domain is not already available, there are three clean options:

Option 1 — A new domain, registered inside AWS (simplest)

- We register a fresh domain through AWS for roughly \$12–15 per year, managed entirely within your AWS account.
- Nothing to coordinate with an outside provider; everything sits under your billing.

Option 2 — A sub-address of your existing company domain (cheapest & fastest)

- If Sunshine already owns a company domain, we simply use a sub-address such as **finance.yourcompany.com**.
- Your IT team makes one small DNS entry pointing to the server — a two-minute change, no purchase needed.
- This is the preferred route *if you are happy to let us use a sub-address*.

Option 3 — We hold a domain on your behalf (interim)

- We register and manage a domain temporarily and hand ownership over to you later. A stop-gap only.

Please confirm: does Sunshine already own a company domain we may use a sub-address of (Option 2)? If yes, deployment is faster and cheaper. If not, we recommend Option 1.

What happens next

- You confirm the domain choice above, and that AWS access is available for our engineer.
- Our engineer provisions the server, deploys the application, and connects the domain with HTTPS.
- We run sign-in and submission tests together, then hand over the live web address.

One point to note for transparency

Running on a single server keeps things simple and cost-effective, which suits a team of your size. The trade-off is that if that one server were ever to fail, the app would be briefly unavailable until it recovers. We reduce this risk with automatic daily backups (snapshots) and an auto-recovery setting that restarts the server by itself. Should you later need guaranteed always-on availability, the same setup extends to a second server without any redesign.

A companion technical runbook has been prepared separately for the engineer carrying out the deployment.
